Main Takeaways From Previous Lecture

- Convolutions can provide
 - local interactions in spacial/temporal dimensions
 - shift invariance
 - *much* less parameters than a fully connected layer
- Usually repeated 3×3 convolutions are enough, no need for larger filter sizes.
- When pooling is performed, double the number of channels (i.e., the first convolution following the pooling layer will have twice as many output channels).
- If your network is deep enough (the last hidden neurons have a large receptive fields), final fully connected layers are not needed, and global average pooling is enough.
- Batch normalization is a great regularization method for CNNs, allowing removal/decrease of dropout and L^2 regularization.
- Small weight decay (i.e., L^2 regularization) of usually 1e-4 is still useful for regularizing convolutional kernels.

ResNet – 2015 (3.6% ILSVRC top-5 error)

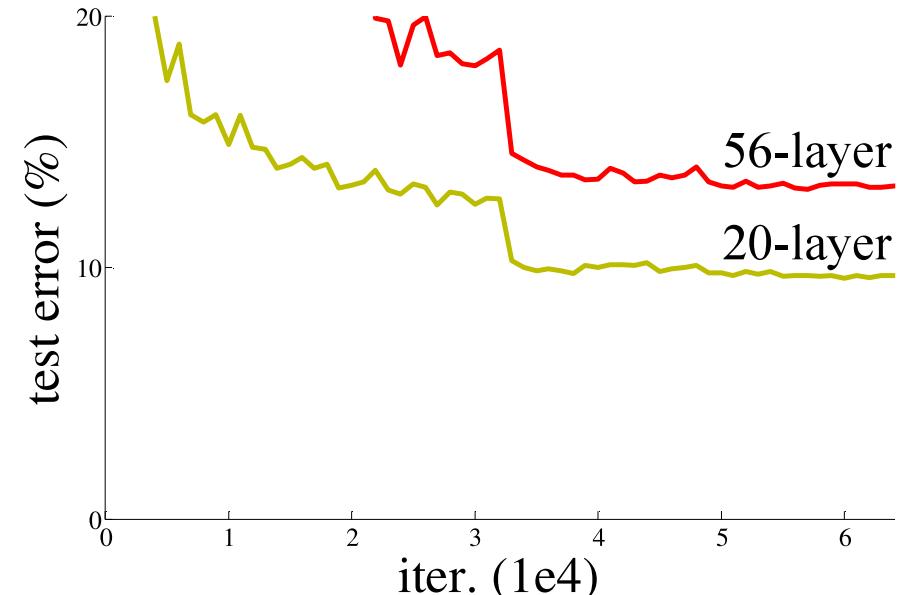

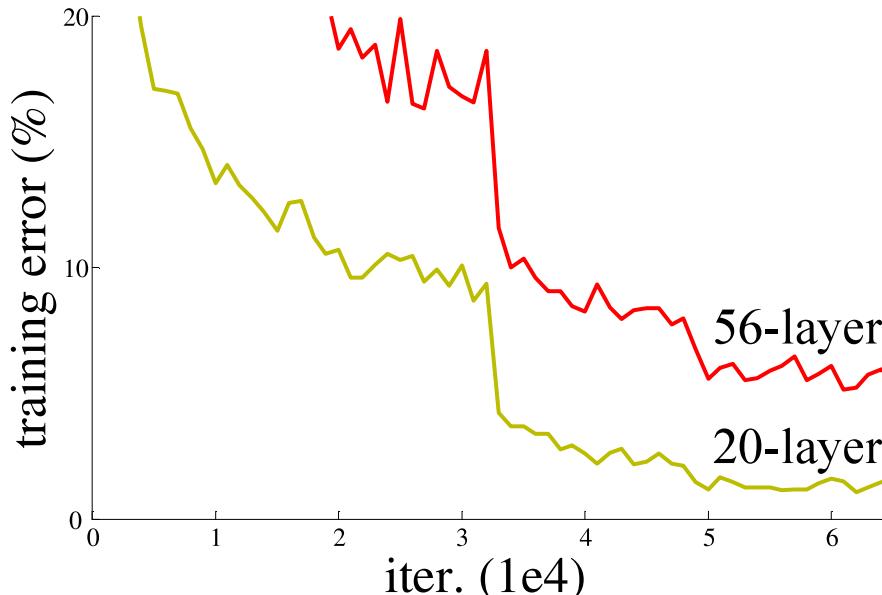

Figure 1. Training error (left) and test error (right) on CIFAR-10 with 20-layer and 56-layer “plain” networks. The deeper network has higher training error, and thus test error. Similar phenomena on ImageNet is presented in Fig. 4.

Figure 1 of “Deep Residual Learning for Image Recognition”, <https://arxiv.org/abs/1512.03385>

ResNet – 2015 (3.6% ILSVRC top-5 error)

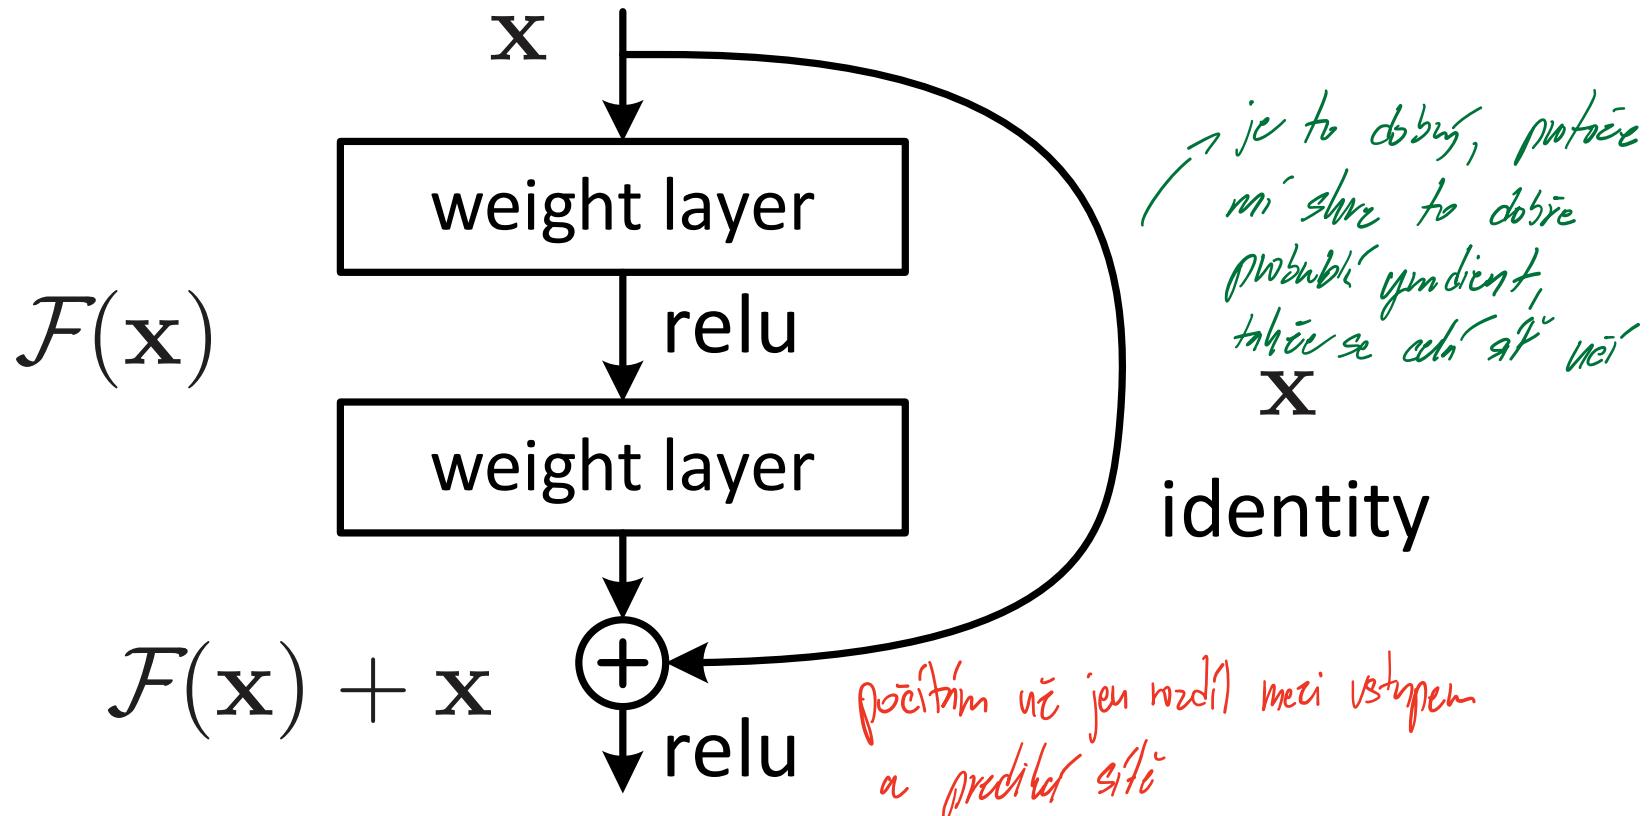

Figure 2. Residual learning: a building block.

Table 1 of "Deep Residual Learning for Image Recognition", <https://arxiv.org/abs/1512.03385>

ResNet – 2015 (3.6% ILSVRC top-5 error)

The residual connections cannot be applied directly when number of channels increases.

The authors considered several alternatives, and chose the one where in case of channels increase a 1×1 convolution + BN is used on the projections to match the required number of channels. The required spacial resolution is achieved by using stride 2.

Figure 3 of "Deep Residual Learning for Image Recognition", <https://arxiv.org/abs/1512.03385>

ResNet – 2015 (3.6% ILSVRC top-5 error)

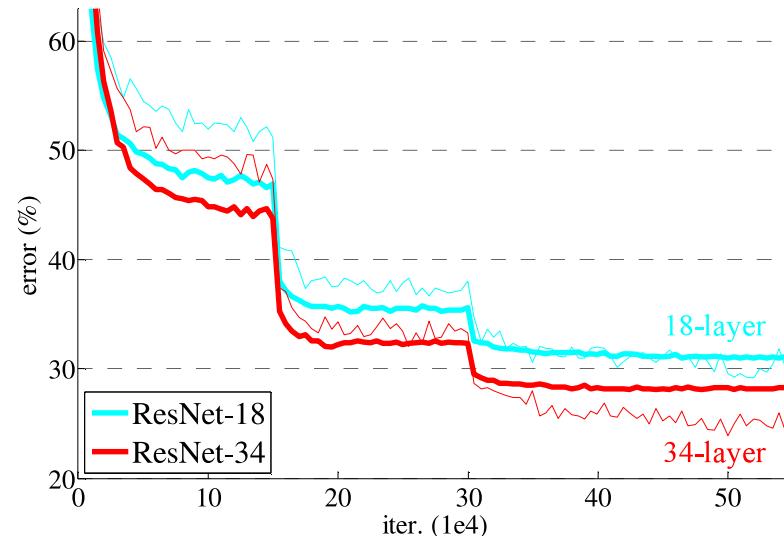

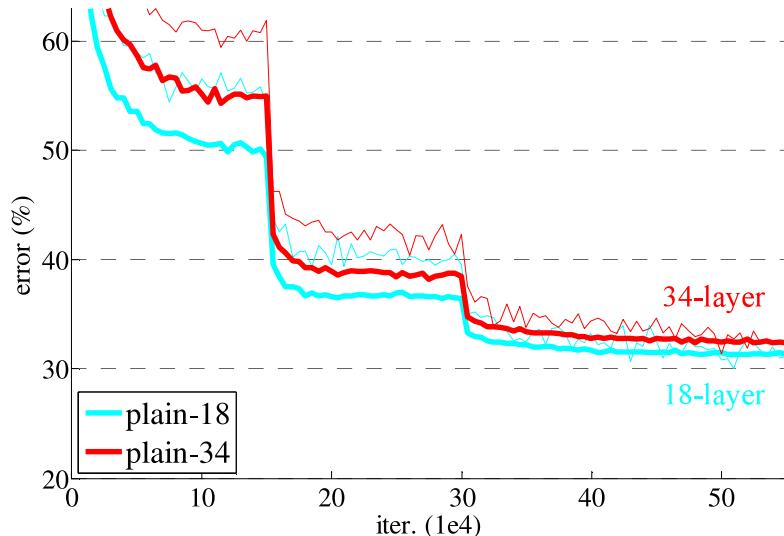

Figure 4. Training on **ImageNet**. Thin curves denote training error, and bold curves denote validation error of the center crops. Left: plain networks of 18 and 34 layers. Right: ResNets of 18 and 34 layers. In this plot, the residual networks have no extra parameter compared to their plain counterparts.

Figure 4 of "Deep Residual Learning for Image Recognition", <https://arxiv.org/abs/1512.03385>

ResNet – 2015 (3.6% ILSVRC top-5 error)

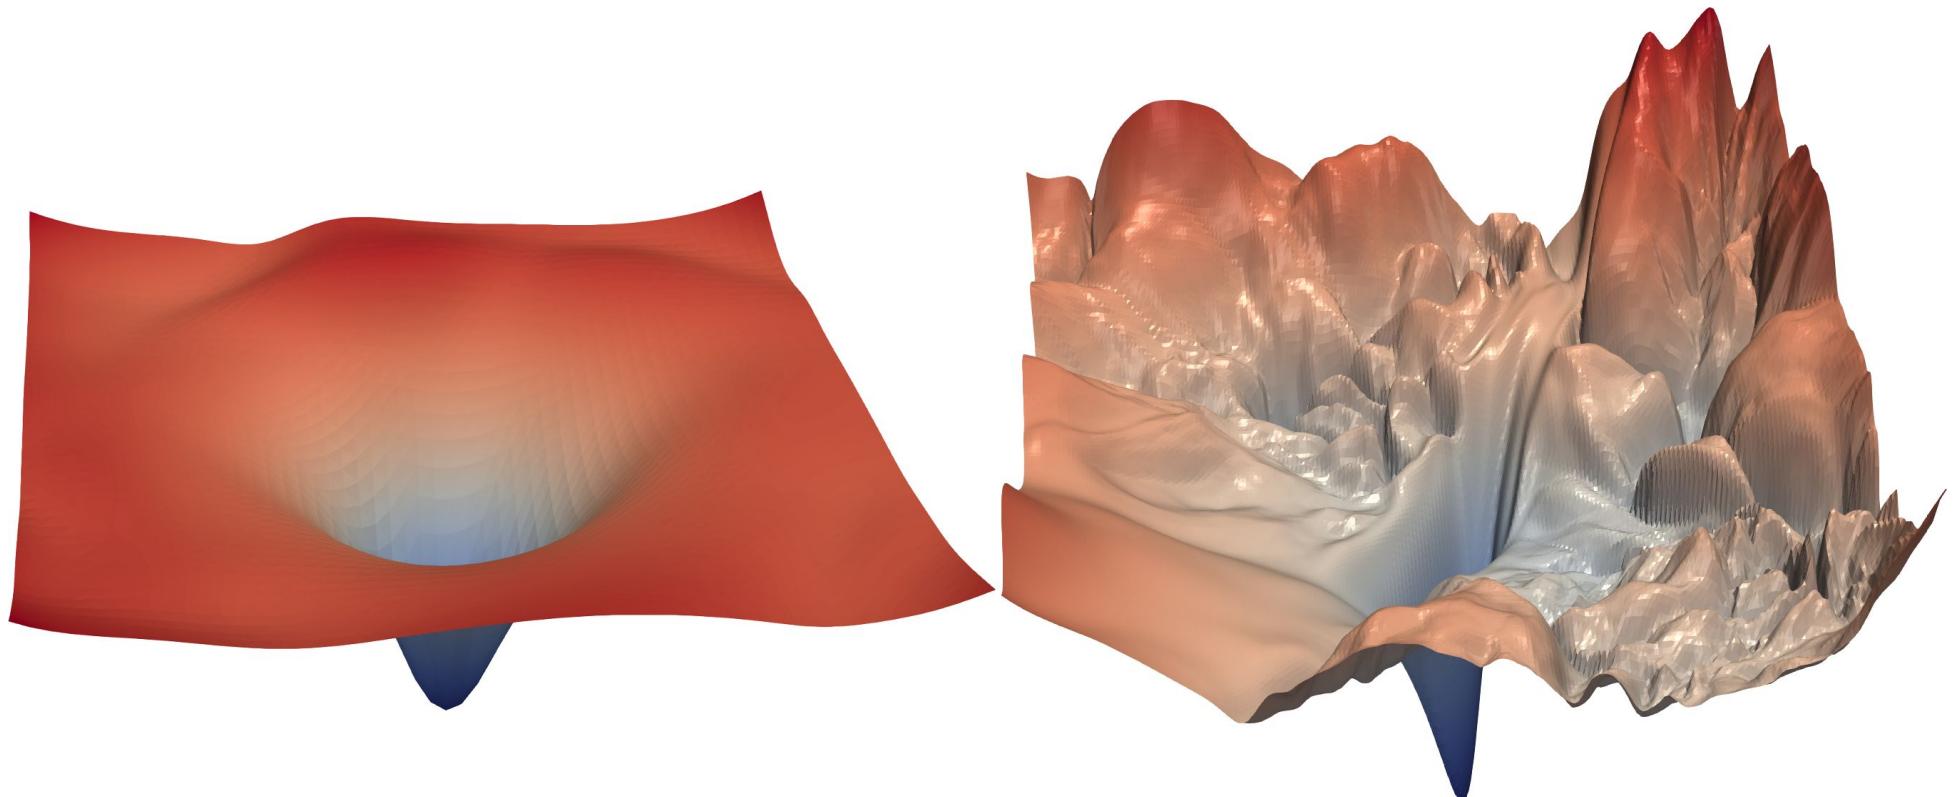

Figure 1 of "Visualizing the Loss Landscape of Neural Nets", <https://arxiv.org/abs/1712.09913>

ResNet – 2015 (3.6% ILSVRC top-5 error)

Training details:

- batch normalizations after each convolution and before activation
- SGD with batch size 256 and momentum of 0.9
- learning rate starts with 0.1 and “is divided by 10 when the error plateaus”
 - 600k training iterations are used (120 epochs, each containing 1.281M images)
 - according to one graph (and to their later paper) they decay at 25% and 50% of the training, so after epochs 30 and 60
 - other concurrent papers also use exponential decay or 25%-50%-75%
- no dropout, weight decay 0.0001
- during training, an image is resized with its shorter side randomly sampled in the range [256, 480], and a random 224×224 crop is used
- during testing, 10-crop evaluation strategy is used
 - for the best results, the scores across multiple scales are averaged – the images are resized so that their smaller size is in $\{224, 256, 384, 480, 640\}$

ResNet – 2015 (3.6% ILSVRC top-5 error)

method	top-1 err.	top-5 err.
VGG [41] (ILSVRC'14)	-	8.43 [†]
GoogLeNet [44] (ILSVRC'14)	-	7.89

Table 4 of "Deep Residual Learning for Image Recognition", <https://arxiv.org/abs/1512.03385>

method	top-5 err. (test)
VGG [41] (ILSVRC'14)	7.32
GoogLeNet [44] (ILSVRC'14)	6.66
VGG [41] (v5)	6.8
PReLU-net [13]	4.94
BN-inception [16]	4.82
ResNet (ILSVRC'15)	3.57

Table 5. Error rates (%) of **ensembles**. The top-5 error is on the test set of ImageNet and reported by the test server.

Table 5 of "Deep Residual Learning for Image Recognition", <https://arxiv.org/abs/1512.03385>

The ResNet-34 B uses the 1×1 convolution on residual connections with different number of input and output channels; ResNet-34 C uses this convolution on all residual connections. Variant B is used for ResNet-50/101/152.

ResNet Ablations – Shortcuts

The authors of ResNet published an ablation study several months after the original paper.

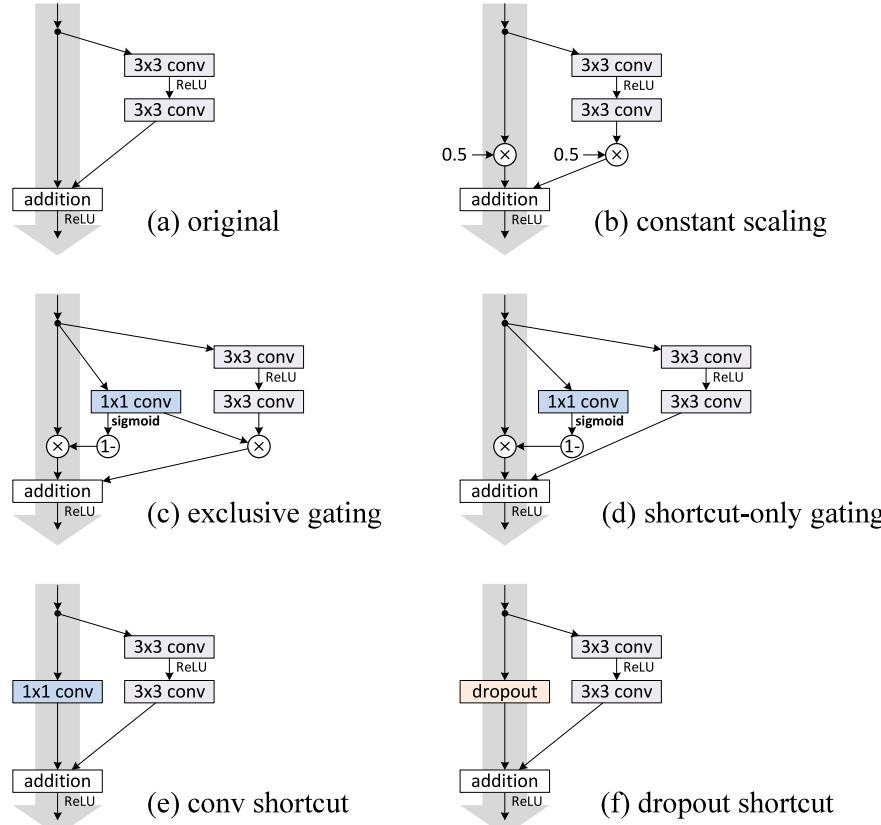

Figure 2 of "Identity Mappings in Deep Residual Networks",
<https://arxiv.org/abs/1603.05027>

Table 1. Classification error on the CIFAR-10 test set using ResNet-110 [1], with different types of shortcut connections applied to all Residual Units. We report “fail” when the test error is higher than 20%.

case	Fig.	on shortcut	on \mathcal{F}	error (%)	remark

PyramidNet

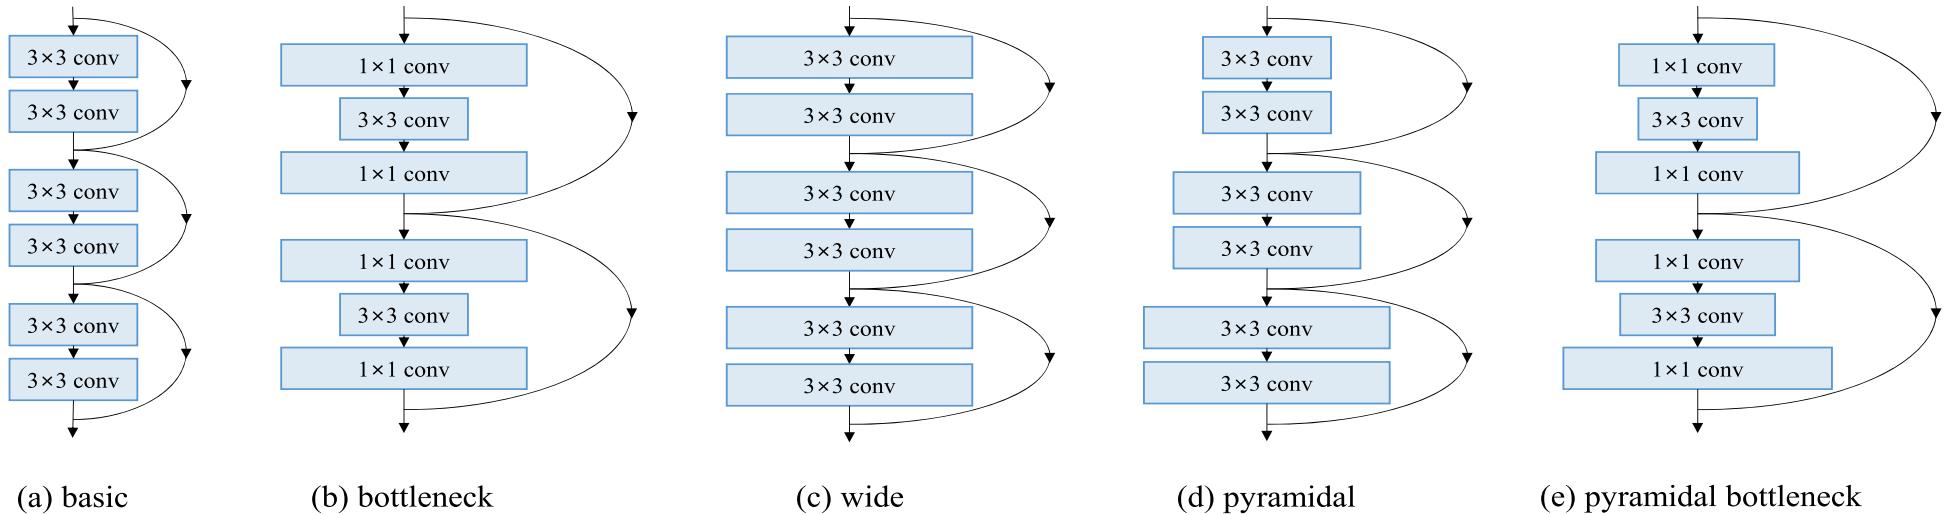

Figure 1 of "Deep Pyramidal Residual Networks", <https://arxiv.org/abs/1610.02915>

PyramidNet – Growth Rate

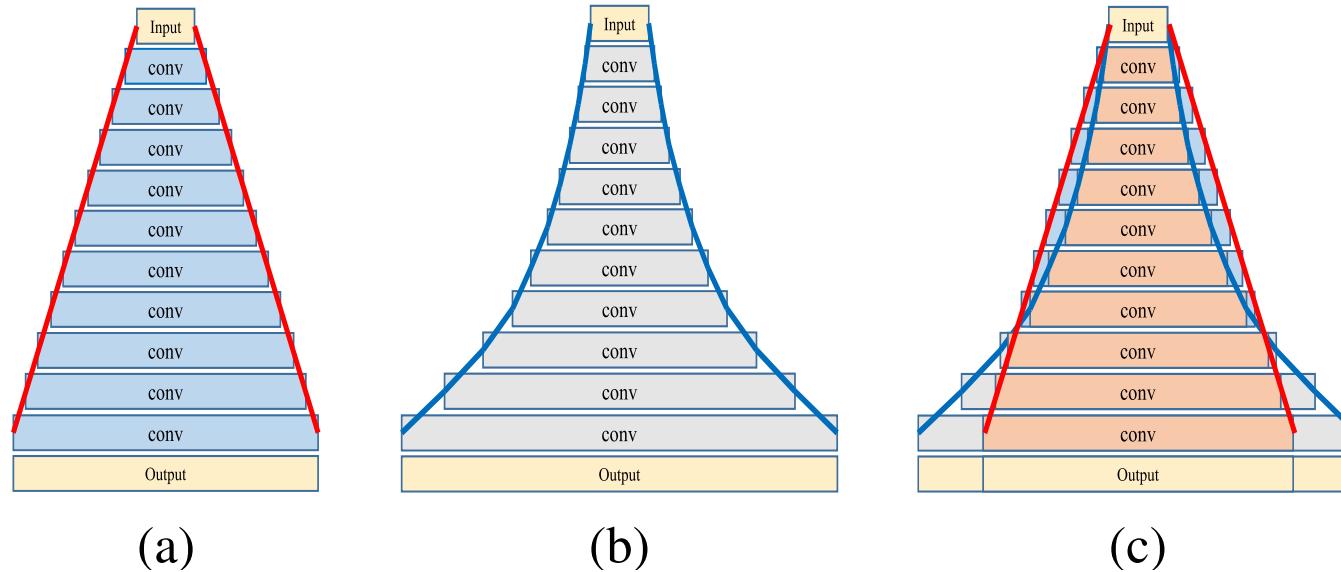

Figure 2 of "Deep Pyramidal Residual Networks", <https://arxiv.org/abs/1610.02915>

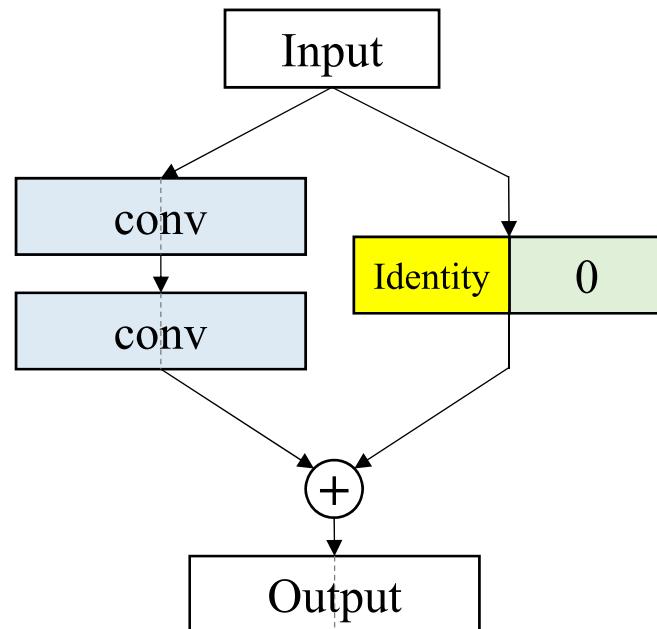

In architectures up until now, number of filters doubled when spacial resolution was halved.

Such exponential growth would suggest gradual widening rule $D_k = \lfloor D_{k-1} \cdot \alpha^{1/N} \rfloor$.

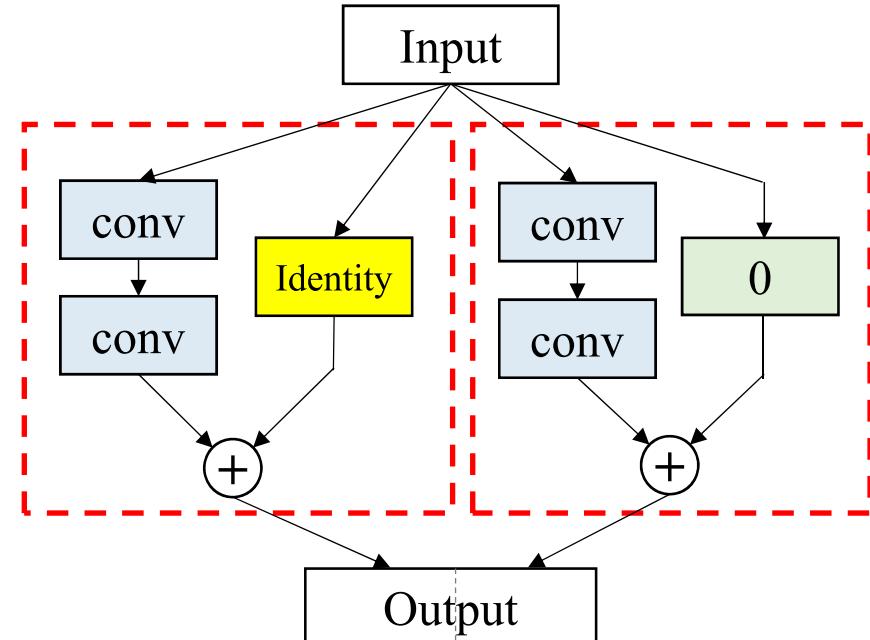

However, the authors employ a linear widening rule $D_k = \lfloor D_{k-1} + \alpha/N \rfloor$, where D_k is number of filters in the k -th out of N convolutional block and α is number of filters to add in total.

PyramidNet – Residual Connections

No residual connection can be a real identity – the authors propose to zero-pad missing channels, where the zero-pad channels correspond to newly computed features.

tahle nechci zadávat, protože to dřív lokal features.

We drop a whole block (but not the residual connection) with probability $1 - p_l$. During inference, we multiply the block output by p_l to compensate; or we can use the alternative approach like in regular dropout, where we divide the activation by p_l during training only.

All p_l can be set to a constant, but more effective approach is to utilize a simple linear decay $p_l = 1 - \frac{l}{L}(1 - p_L)$, where p_L is the final probability of the last layer, motivated by the intuition that the initial blocks extract low-level features utilized by the later layers, and should therefore be present.

DropBlock

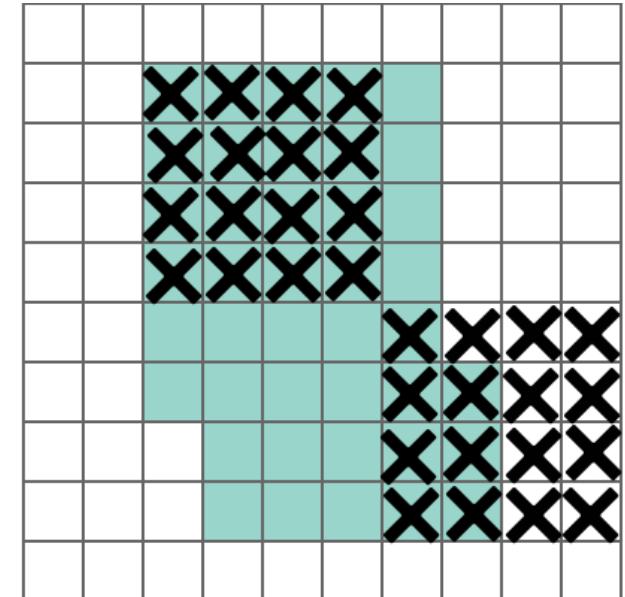

Dropout drops individual values, SpatialDropout drops whole channels, DropBlock drops rectangular areas in all channels at the same time.

(a)

(b)

(c)

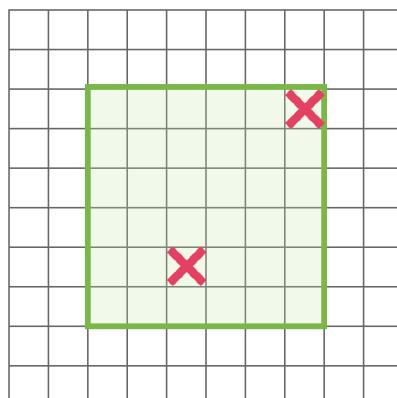

Figure 1 of "DropBlock: A regularization method for convolutional networks", <https://arxiv.org/abs/1810.12890>

The authors mention that they also tried applying DropBlock in every channel separately, but that masking all channels equally “tends to work better in our experiments”.

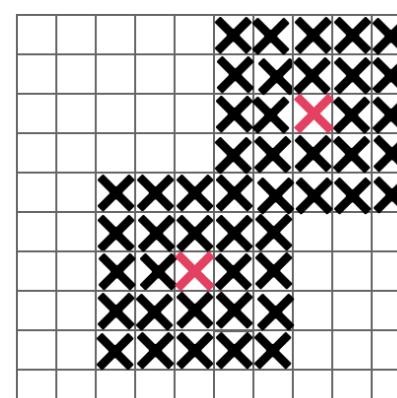

DropBlock

Algorithm 1 DropBlock

- 1: **Input:** output activations of a layer (A), $block_size$, γ , $mode$
 - 2: **if** $mode == Inference$ **then**
 - 3: **return** A
 - 4: **end if**
 - 5: Randomly sample mask M : $M_{i,j} \sim Bernoulli(\gamma)$
 - 6: For each zero position $M_{i,j}$, create a spatial square mask with the center being $M_{i,j}$, the width, height being $block_size$ and set all the values of M in the square to be zero (see Figure 2).
 - 7: Apply the mask: $A = A \times M$
 - 8: Normalize the features: $A = A \times \text{count}(M) / \text{count_ones}(M)$
-

(a)

(b)

Figure 2 of "DropBlock: A regularization method for convolutional networks", <https://arxiv.org/abs/1810.12890>

DropBlock

The authors have chosen $block\ size=7$ and also employ linear schedule of the *keep probability*, which starts at 1 and linearly decays until the target value is reached at the end of training.

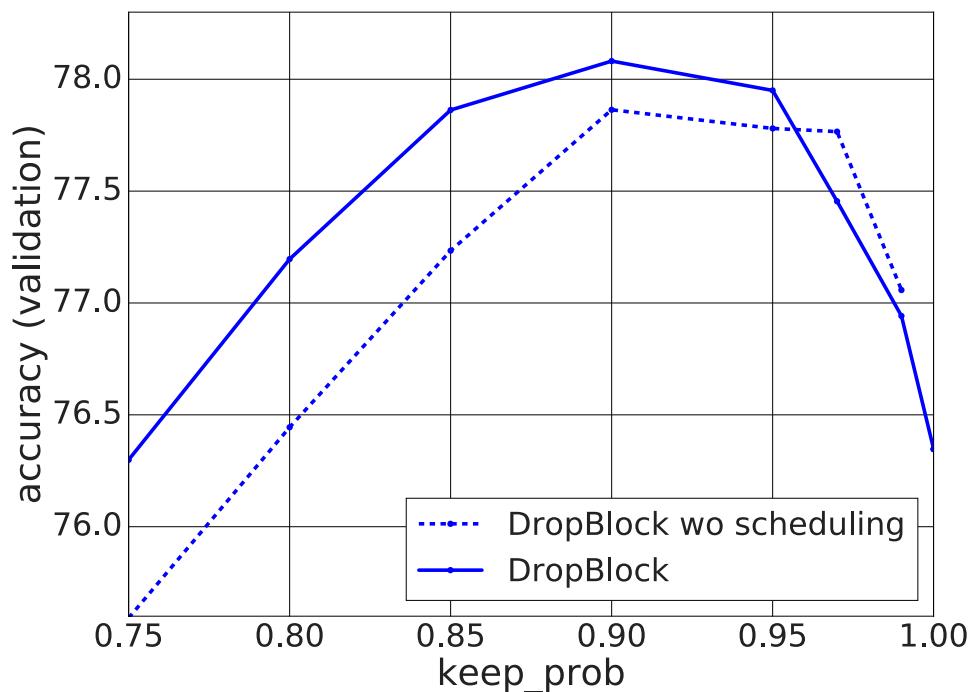

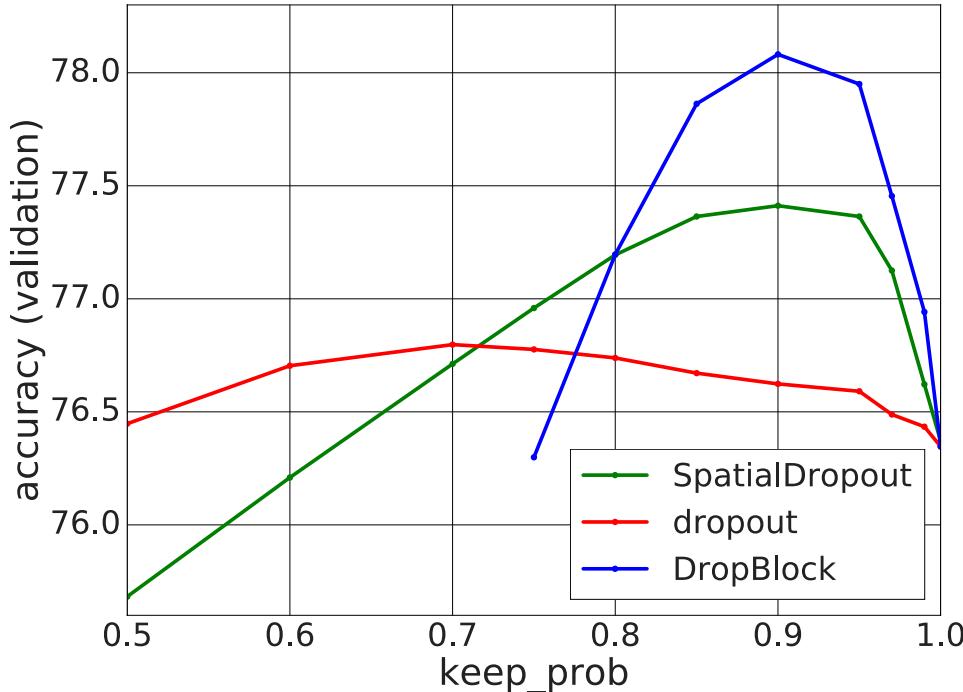

Figure 3 of "DropBlock: A regularization method for convolutional networks", <https://arxiv.org/abs/1810.12890>

To perform CutMix:

- First we sample λ uniformly from $(0, 1)$.
- We sample bounding box center uniformly.
- Width and height are set to $W\sqrt{\lambda}$, $H\sqrt{\lambda}$.
- Labels are combined as $\lambda y_A + (1 - \lambda)y_B$.

Squeeze and Excitation

The ILSVRC 2017 winner was SENet, *Squeeze and Excitation Network*, augmenting existing architectures by a **squeeze and excitation** block, which learns to emphasise informative channels and suppress less useful ones according to global information.

- **squeeze (global information embedding)** computes the average value of every channel;
- **excitation (adaptive recalibration)** computes a weight for every channel using a sigmoid activation function and multiplies the corresponding channel with it. To not increase the number of parameters too much (by C^2), an additional small hidden layer with $C/16$ neurons is employed (to reduce the additional parameters to $C^2/8$ only).

Mobile Inverted Bottleneck Convolution

When designing convolutional neural networks for mobile phones, the following **mobile inverted bottleneck** block was proposed.

- Regular convolution is replaced by **separable convolution**, which consists of
 - a **depthwise separable** convolution (for example 3×3) acting on each channel separately (which reduces time and space complexity of a regular convolution by a factor equal to the number of channels);
 - a **pointwise** 1×1 convolution acting on each position independently (which reduces time and space complexity of a regular convolution by a factor of $3 \cdot 3$).
 ↳ *hierfür kann ich 1x1-Kernel benutzen*
- jeden Kanal hauptsächlich parallel*
- reduziert Komplexität*
- Netzwerkbaublock*

- (a) Residual block*
- (b) Inverted residual block*
-

Figure 3 of "MobileNetV2: Inverted Residuals and Linear Bottlenecks", <https://arxiv.org/abs/1801.04381>

Mobile Inverted Bottleneck Convolution

The mobile inverted bottleneck convolution is denoted for example as $MBConv6\ k3\times 3$, where the 6 denotes expansion factor after the bottleneck and 3×3 is the kernel size of the separable convolution.

Furthermore, the mobile inverted bottleneck convolution can be augmented with squeeze and excitation blocks.

EfficientNet

→ velmi dobré výsledky, ale ohromitelsky menší, levíši na training a inference

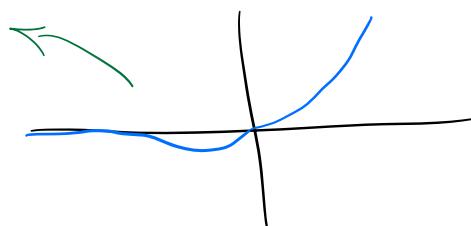

In 2019, very performant and efficient convolutional architecture **EfficientNet** was proposed.

The EfficientNet architecture was created using a multi-objective neural architecture search that optimized both accuracy and computation complexity.

The resulting network is denoted as **EfficientNet-B0** baseline network.

It was trained using RMSProp with $\beta=0.9$ and momentum 0.9, weight decay 1e-5, and initial learning rate 0.256 decayed by 0.97 every 2.4 epochs. Dropout with dropout rate 0.2 is used on the last layer, stochastic depth with survival probability 0.8 is employed, and swish(\mathbf{x}) $\stackrel{\text{def}}{=} \mathbf{x} \odot \sigma(\mathbf{x})$ activation function is utilized.

EfficientNet – Compound Scaling

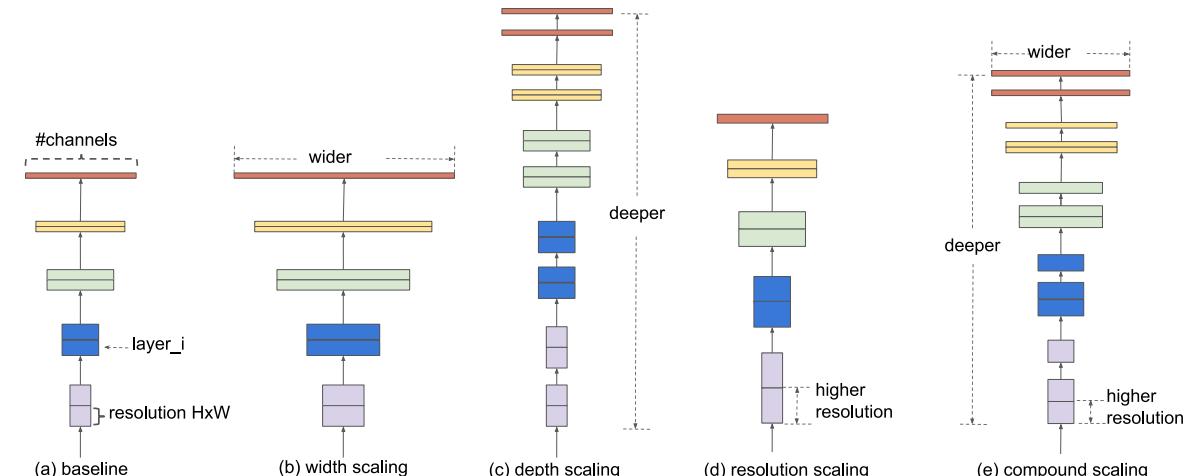

Figure 2 of "EfficientNet: Rethinking Model Scaling for Convolutional Neural Networks", <https://arxiv.org/abs/1905.11946>

To effectively scale the network, the authors propose a simultaneous increase of three qualities:

- **width**, which is the number of channels;
- **depth**, which is the number of layers;
- **resolution**, which is the input image resolution.

By a grid search on a network with double computation complexity, the best trade-off of scaling width by 1.1, depth by 1.2 and resolution by 1.15 was found ($1.1^2 \cdot 1.2 \cdot 1.15^2 \approx 2$).

EfficientNetV2

– jeden z těch velmi dobrých sítí na řešení klasifikace obrazů.

In April 2021, an improved version of EfficientNet, **EfficientNetV2**, was published. It is currently one of very good CNNs available for image recognition.

The improvements between EfficientNet and EfficientNetV2 are not large:

- The separable convolutions have fewer parameters, but are slow to execute on modern hardware. The authors therefore “fuse” the 1×1 convolution and a 3×3 depthwise convolution into a regular convolution, which has more parameters and require more computation, but is in fact executed faster.
- Very large images make training very slow. EfficientNetV2 avoids aggressively scaling the image sizes, limiting maximum image size to 480.
- The authors utilize progressive training – the image size is gradually increased during training, as is the regularization strength (dropout, mixup, RandAugment magnitude).

Table 7 of "EfficientNetV2: Smaller Models and Faster Training", <https://arxiv.org/abs/2104.00298>

Transfer Learning

In many situations, we would like to utilize a model trained on a different dataset – generally, this cross-dataset usage is called **transfer learning**.

In image processing, models trained on ImageNet are frequently used as general **feature extraction models**.

The easiest scenario is to take a ImageNet model, drop the last classification layer, and use the result of the global average pooling as image features. The ImageNet model is not modified during training.

For efficiency, we may precompute the image features **once** and reuse it later many times.

Transfer Learning – Finetuning

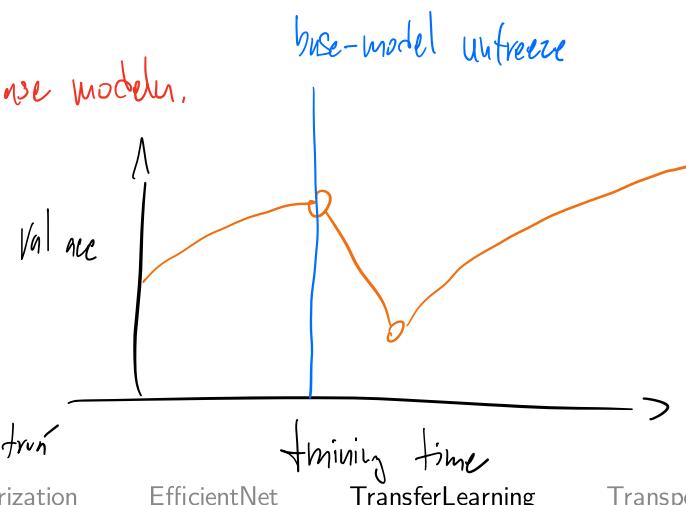

After we have successfully trained a network employing an ImageNet model, we may improve performance further by **finetuning** – training the full network including the ImageNet model, allowing the feature extraction to adapt to the current dataset.

- The layers after the ImageNet models **should** be already trained to convergence.
- Usually a smaller learning rate is necessary, because the original model probably finished training with a very small learning rate. A good starting point is one tenth of the original starting learning rate (therefore, 0.0001 for Adam).
- We have to think about batch normalization, data augmentation, or other regularization techniques.

„fukáte hrych jinak mohl zahrát hodn' silly base modelu.“

to je fin, i.e se uvolní trénink

a ten batch-norm tam jinak nezahráje
už stěží nic být s těmi výhledy, faktive k adaptace trén

Transposed Convolution

So far, the convolution operation produces either an output of the same size, or it produced a smaller one if stride was larger than one.

In order to come up with **upsampling convolution**, we start by considering how a gradient is backpropagated through a fully connected layer and a regular convolution.

In a fully connected layer without activation:

- during the forward pass, the input \mathbf{X} is multiplied by the weight matrix \mathbf{W} as $\mathbf{X}\mathbf{W}$;
- during the backward pass, the gradient \mathbf{G} is multiplied by the *transposed* weight matrix as $\mathbf{G}\mathbf{W}^T$.

Transposed Convolution

Analogously, in a convolutional layer without activation:

- during the forward pass, the cross-correlation operation between input \mathbf{I} and kernel \mathbf{K} is performed as

$$(\mathbf{K} \star \mathbf{I})_{i,j,o} = \sum_{m,n,c} \mathbf{I}_{i \cdot S + m, j \cdot S + n, c} \mathbf{K}_{m,n,c,o};$$

○ → tady jdou přes vstupní kanály

- during the backward pass, we obtain $\mathbf{G}_{i,j,o} = \frac{\partial L}{\partial (\mathbf{K} \star \mathbf{I})_{i,j,o}}$, and we need to backpropagate it to obtain $\frac{\partial L}{\partial \mathbf{I}_{i,j,c}}$. It is not difficult to show that

$$\frac{\partial L}{\partial \mathbf{I}_{i,j,c}} = \sum_{i',m} \sum_{j',n} \sum_{o} \mathbf{G}_{i',j',o} \mathbf{K}_{m,n,c,o}.$$

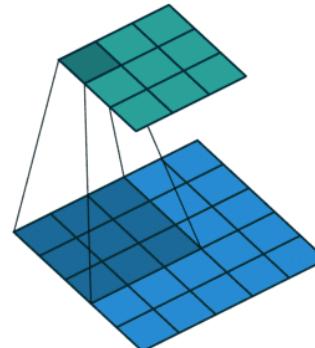

○ → tady jdou přes vstupní kanály

This operation is called **transposed** or **upsampling** convolution and stride greater than one makes the output larger, not smaller.

- **same**, stride=2, regular:

transposed:

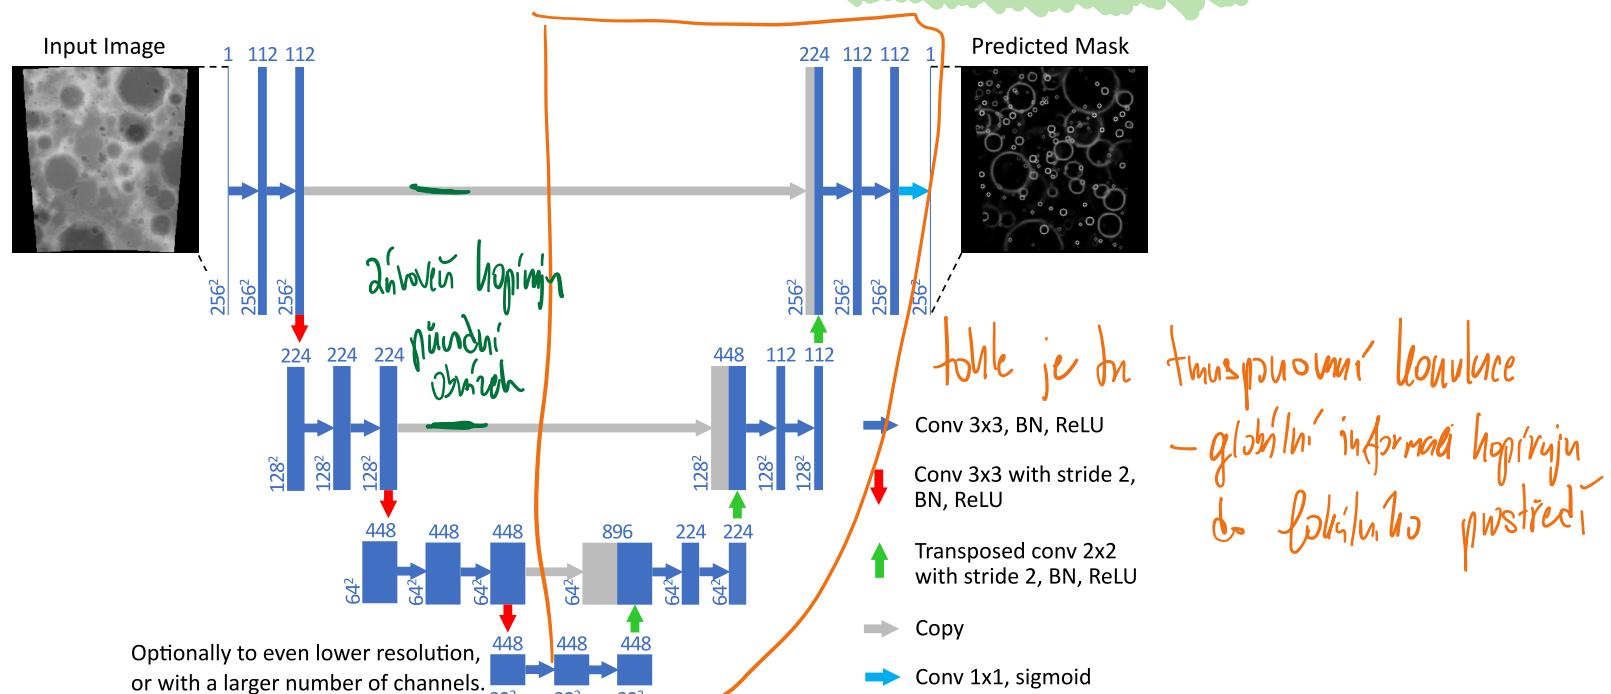

https://github.com/vdumoulin/conv_arithmetic

https://github.com/vdumoulin/conv_arithmetic

Transposed Convolution

Given that the transposed convolution must be implemented for efficient backpropagation of a regular convolution, it is usually available for direct usage in neural network frameworks.

It is frequently used to perform upscaling of an image, as an “inverse” operation to pooling (or convolution with stride > 1), which is useful for example in *image segmentation*:
